

1

Obtain reference C by inversion

Fit the ice-flow model to observed velocity across the sector.

This includes observations inside the later test regions.

2

Withhold a region from MLP training and validation

For square tests, exclude the central square and its buffer.

For regional tests, exclude the selected region.

3

Train MLPs to predict C from local predictors

Use reference C as the target outside the excluded region.

Do not supply observed velocity as an MLP predictor.

4

Combine predicted C and simulate velocity

Take the median of ten predictions at each mesh vertex.

Use this C field in one Icepack simulation.

5

Evaluate velocity in the withheld region

Compare modeled velocity with observed velocity.

Also evaluate the uniform-C and inversion references.
